# ON THE ZEROS OF THE SOLUTIONS TO NONLINEAR HYPERBOLIC EQUATIONS WITH DELAYS 

Z. A. Petrova*, D. P. Mishev

Abstract. We consider the nonlinear hyperbolic equation with delays

$$
u_{x y}+\lambda u_{x y}(x-\sigma, y-\tau)+c\left(x, y, u, u_{x}, u_{y}\right)=f(x, y) .
$$

We obtain sufficient conditions for oscillation of the solutions of problems of Goursat in the case, where $\lambda \geq 0$.

## 1. Introduction

Oscillation theory for hyperbolic equations and especially with deviating arguments is still in initial stage. In [12] Yoshida pointed out that characteristic initial value problems for hyperbolic equations were considered in [1] - [4], [10, 11] and forced oscillations of solutions to hyperbolic equations were investigated by Kreith et al. [3] and Mishev [5].

Many results in the oscillation theory for equations with deviating arguments are similar to the respective results for equations without deviating arguments following the same ideas. In this paper we use the method due to Yoshida [12] to obtain the analogue of his result in the case with deviations. More exactly, we adapt the obtained there sufficient conditions in such a way that under them every solution to certain characteristic initial value problems for hyperbolic equations

[^0]with constant deviations has a zero in bounded domains defined as in [12]. We also mention that this method leads to sufficient conditions for nonexistence of positive and monotonically increasing in every argument solutions as well as which are negative and monotonically decreasing in every argument solutions in certain sets if $-1 \leq \lambda \leq 0$ (see [7]).

We consider the following characteristic initial value problem

$$
\begin{array}{r}
u_{x y}(x, y)+\lambda u_{x y}(x-\sigma, y-\tau)+c\left(x, y, u, u_{x}, u_{y}\right)=f(x, y), x>0, y>0  \tag{1}\\
u(x, y)=p(x, y), \\
u(x, y) \in \mathbf{S}_{1} \equiv[-\sigma, \infty) \times[-\tau, 0] \\
u(x, y)=q(x, y), \quad \forall(x, y) \in \mathbf{S}_{\mathbf{2}} \equiv[-\sigma, 0] \times[-\tau, \infty)
\end{array}
$$

where $\lambda, \sigma$ and $\tau$ are nonnegative numbers. We define

$$
\begin{aligned}
& Q_{\rho}=\left\{x>0, y>0: L x+k^{2} L^{-1} y>L \rho\right\} \\
& Q\left(t_{1}, t_{2}\right]=\left\{x>0, y>0: L t_{1}<L x+k^{2} L^{-1} y \leq L t_{2}\right\}
\end{aligned}
$$

where $\rho$ and $t_{1} \leq t_{2}$ are nonnegative numbers and $k$ and $L$ are positive numbers.
We state the conditions $(\mathbf{H})$ :

$$
\text { H1. } \quad c(x, y, \xi, \eta, \zeta) \in C\left(\overline{Q_{\rho}} \times \mathbf{R}^{\mathbf{3}}, \mathbf{R}\right)
$$

H2. $\quad f(x, y) \in C\left(\overline{Q_{\rho}}, \mathbf{R}\right) ; p(x, y), q(x, y) \in C^{1}\left(\mathbf{R}^{2}, \mathbf{R}\right)$;
H3. $\quad p(x, y)=q(x, y) \quad \forall(x, y) \in[-\sigma, 0] \times[-\tau, 0]$;
H4. $\quad \xi c(x, y, \xi, \eta, \zeta) \geq 0 \quad \forall(x, y, \xi, \eta, \zeta) \in \overline{Q_{\rho}} \times \mathbf{R}^{3}$.
For every solution $u \in D\left(Q_{\rho}\right) \equiv C^{2}\left(Q_{\rho}\right) \bigcap C^{1}\left(\overline{Q_{\rho}}\right)$ to (1) we define

$$
\begin{align*}
& w_{n}(t)=w(t)+\lambda w_{d}(t)  \tag{3}\\
& \text { where } \quad w(t)=t^{-1} \int_{0}^{t} u\left(\xi, L^{2} k^{-2}(t-\xi)\right) d \xi  \tag{4}\\
& w_{d}(t)=t^{-1} \int_{0}^{t} u\left(\xi-\sigma, L^{2} k^{-2}(t-\xi)-\tau\right) d \xi  \tag{5}\\
& \text { and } W_{n}(\tilde{t}, t)=\tilde{t} w_{n}(\tilde{t})+\left(w_{n}(\tilde{t})+\tilde{t} w_{n}^{\prime}(\tilde{t})\right)(t-\tilde{t}) \\
& +\int_{\tilde{t}}^{t}(t-s)\left(p_{n}^{\prime}(s)+L^{2} k^{-2} q_{n}^{\prime}\left(L^{2} k^{-2} s\right)\right. \\
& \left.+L^{2} k^{-2} \int_{0}^{s} f\left(\xi, L^{2} k^{-2}(s-\xi)\right) d \xi\right) d s \\
& \text { where } \quad p_{n}(t)=p(t, 0)+\lambda p(t-\sigma,-\tau) \\
& \text { and } \quad q_{n}\left(L^{2} k^{-2} t\right)=q\left(0, L^{2} k^{-2} t\right)+\lambda q\left(-\sigma, L^{2} k^{-2} t-\tau\right) \text {. }
\end{align*}
$$

On the zeros of the solutions to nonlinear hyperbolic equations with Delays 191

We continue the introduction with the geometrical interpretation of all the above sets and the functions $w(t)$ and $w_{d}(t)$. This interpretation will be done in three steps:

I description of the sets $Q_{\rho}$ and $Q\left(t_{1}, t_{2}\right]$;
II interpretation of the functions $w(t)$ and $w_{d}(t)$;
III explanation of the link between the set $Q\left(t_{1}, t_{2}\right]$ and the functions $w(t)$ and $w_{d}(t)$.

We deal with the family of lines:

$$
\begin{equation*}
l_{t}: y=L^{2} k^{-2}(t-x), \quad t \geq 0 \tag{9}
\end{equation*}
$$

Remark 1. In fact, the equation of Descartes (9) shows that this is a family of lines of level, which depends on the parameter $t$. Moreover, a bigger parameter corresponds to a

$$
\begin{align*}
& \text { higher line. In other words, if } \quad 0 \leq t_{1} \leq t_{2}  \tag{10}\\
& \text { then the line }  \tag{11}\\
& \begin{array}{l}
l_{t_{1}} \\
\text { is above the line }
\end{array} l_{t_{2}}: y=L^{2} k^{-2}\left(t_{1}-x\right)  \tag{12}\\
& L^{2} k^{-2}\left(t_{2}-x\right) .
\end{align*}
$$

Remark 2. Now we are ready to describe the defined here sets. Let

$$
A_{t}=l_{t} \bigcap O_{x} \quad \text { and } \quad B_{t}=l_{t} \bigcap O_{y}
$$

Then the set $Q_{\rho}$ is the part of the first quadrant, which is above the line $A_{\rho} B_{\rho}$. Also, the set $Q\left(t_{1}, t_{2}\right]$ is the union of the open trapezoid $A_{t_{1}} A_{t_{2}} B_{t_{2}} B_{t_{1}}$ and the open segment $A_{t_{2}} B_{t_{2}}$.

We continue with the second step. The family of lines (9) could be parametrized in the following way:

$$
l_{t}:\left\{\begin{array}{l}
x=\xi, \quad \xi \in(-\infty,+\infty)  \tag{13}\\
y=L^{2} k^{-2}(t-\xi)
\end{array}\right.
$$

Obviously, (13) leads to the following parametrization of the segment $A_{t} B_{t}$ :

$$
A_{t} B_{t}:\left\{\begin{array}{l}
x=\xi, \quad \xi \in[0, t]  \tag{14}\\
y=L^{2} k^{-2}(t-\xi)
\end{array}\right.
$$

The comparison between (14) and (4) gives us that the function $w(t)$ is an average of the solution $u(x, y)$ on the segment $A_{t} B_{t}$. The function $w_{d}(t)$ is an average of the same solution on the segment

$$
C_{t_{*}} D_{t_{*}}:\left\{\begin{array}{l}
x=\xi-\sigma, \quad \xi \in[0, t]  \tag{15}\\
y=L^{2} k^{-2}(t-\xi)-\tau
\end{array}\right.
$$

where the points $D_{t_{*}}$ and $C_{t_{*}}$ correspond to the values 0 and $t$ respectively, i. e.

$$
\begin{aligned}
& C_{t_{*}}\left(-\sigma, L^{2} k^{-2} t-\tau\right)=l_{t_{*}} \bigcap\{y=-\tau\} \\
& \text { and } \quad D_{t_{*}}(t-\sigma,-\tau)=l_{t_{*}} \bigcap\{x=-\sigma\}
\end{aligned}
$$

(16) This segment is on the line $l_{t_{*}}: y=L^{2} k^{-2}\left(t_{*}-x\right)$,
(17) where $t_{*}=t-\sigma-L^{-2} k^{2} \tau=t-\sigma-\theta_{*}, \quad \theta_{*}=L^{-2} k^{2} \tau$.
(18) Let us define the function $\theta(t)=t-\theta_{*}$, which is concerned with $C_{t_{*}}$.

Remark 3. Since $t \geq 0, \sigma \geq 0, \tau \geq 0, L>0$ and $k>0$, then (17) leads to

$$
\begin{equation*}
t_{*} \leq t \tag{19}
\end{equation*}
$$

which is a particular case of (10). Hence, the line $l_{t}$ is always above the line $l_{t_{*}}$ according to Remark 1.

We pass to the third step of the geometrical interpretation, i. e. we shall investigate the link between the function $w_{n}(t)$ and the set $Q\left(t_{1}, t_{2}\right]$. More precisely, we are interested if the open segments $A_{t} B_{t}$ and $C_{t_{*}} D_{t_{*}}$ lie in $Q\left(t_{1}, t_{2}\right]$.

We apply all of the above remarks to conclude that the condition:

$$
\begin{equation*}
0 \leq t_{1} \leq t \leq t_{2} \tag{20}
\end{equation*}
$$

guarantees both that the open segment $A_{t} B_{t}$ is in $Q\left(t_{1}, t_{2}\right]$ and that the open segment $A_{t_{2}} B_{t_{2}}$ is above the open segment $A_{t_{*}} B_{t_{*}}$. In fact, the combination of our conjecture (20) and the inequality (19), which is always fulfilled according to Remark 3 leads to

$$
\begin{equation*}
0 \leq t_{*} \leq t \leq t_{2} \tag{21}
\end{equation*}
$$

Hence, we do not know previously if $0 \leq t_{1} \leq t_{*}$
and we should suppose (22) additionally to be sure that the open segment $A_{t_{*}} B_{t_{*}}$ is above the open segment $A_{t_{1}} B_{t_{1}}$. Let us rewrite (22) taking in attention (17):

$$
\begin{equation*}
\text { which is equivalent to the following inequality : } 0 \leq \tilde{t}_{1} \leq t \tag{24}
\end{equation*}
$$

$$
\begin{equation*}
0 \leq t_{1} \leq t-\sigma-L^{-2} k^{2} \tau \tag{23}
\end{equation*}
$$

$$
\begin{equation*}
\text { where } \quad \tilde{t}_{1}=t_{1}+\sigma+L^{-2} k^{2} \tau=t_{1}+\sigma+\theta_{*} \tag{25}
\end{equation*}
$$

On the zeros of the solutions to nonlinear hyperbolic equations with Delays 193

We extract the above considerations in a special remark, which will be applied in the next section essentially. More exactly, the nonnegative numbers $t_{1} \leq t_{2}$ will be fixed but arbitrary in the second section.

## Remark 4. Let

$$
\begin{equation*}
0 \leq \tilde{t}_{1} \leq t \leq t_{2} \tag{26}
\end{equation*}
$$

Then the open segments $A_{t} B_{t}$ and $A_{t_{*}} B_{t_{*}}$ lie in $Q\left(t_{1}, t_{2}\right]$.
We denote by $U_{t}$ and $V_{t}$ the points on the line $l_{t}$, which correspond to the values $\sigma$ and $\theta(t)$. We do not know in general if

$$
\begin{align*}
& \sigma \in[0, t]  \tag{27}\\
& \text { and } \quad \theta(t) \in[0, t] \tag{28}
\end{align*}
$$

but we shall prove the following lemma taking in attention Remark 4.
Lemma 1. If (26) is fulfilled then (27) and (28) are also fulfilled.
Proof. We replace (25) in (26):

$$
\begin{equation*}
0 \leq t_{1}+\sigma+\theta_{*} \leq t \leq t_{2} \tag{29}
\end{equation*}
$$

Every addend in the left hand side of (29) is nonnegative:

$$
\begin{equation*}
t_{1} \geq 0, \quad \sigma \geq 0 \quad \text { and } \quad \theta_{*} \geq 0 \tag{30}
\end{equation*}
$$

Hence, the first conclusion of the simultaneous consideration of (29) and (30) is

$$
0 \leq \sigma \leq t
$$

which is just (27). The second one is concerned with (18) also:

$$
\begin{equation*}
0 \leq t_{1} \leq t-\theta_{*} \leq t \tag{31}
\end{equation*}
$$

and then (28) follows from (31) immediately.
Definition 1. We say that the function $\varphi(t)$ is oscillating when $t \rightarrow \infty$, if there exists a sequence $\left\{t_{n}\right\}_{n=1}^{\infty}$ such that

$$
\begin{equation*}
\lim _{n \rightarrow \infty} t_{n}=\infty \quad \text { and } \quad \varphi\left(t_{n}\right)=0 \tag{32}
\end{equation*}
$$

Definition 2. We say that the function $\varphi(t)$ is eventually positive (eventually negative), if there exists $c=$ const such that

$$
\begin{equation*}
\varphi(t)>0 \quad(\varphi(t)<0) \quad \forall t \in[c, \infty) \tag{33}
\end{equation*}
$$

Remark 5. In fact, we use the obvious fact that if there is a constant $c$ such that $f(t)$ changes its sign infinitely many times when $t \in[c, \infty)$ and $f(t) \in$ $C([c, \infty), \mathbf{R})$, then the function $f(t)$ is oscillating.

Remark 6. Since in all the bellow our results are for the classical solutions of concrete problems, then the solutions are only of the mentioned three types. It means that it is enough to show that an equation has nor eventually positive neither eventually negative solutions to establish that it has only oscillating solutions.

Here this is possible only in the cases, where $\lambda \geq 0$. We especially underline that the paper of Yoshida [12] is devoted to the situation $\lambda=0$. Our present publication is a generalization of Yoshida [12]. More exactly, the similar results in [12] follow directly from all in the bellow.

Obviously,

$$
\begin{align*}
& t w_{n}(t)=I_{1}(t)+\lambda E_{1}(t)+I_{2}(t)+I_{3}(t)+\lambda E_{3}(t)  \tag{34}\\
& \text { where } \quad I_{1}(t)=\int_{0}^{\sigma} u\left(\xi, L^{2} k^{-2}(t-\xi)\right) d \xi  \tag{35}\\
& E_{1}(t)=\int_{0}^{\sigma} p\left(\xi-\sigma, L^{2} k^{-2}(t-\xi)-\tau\right) d \xi  \tag{36}\\
& I_{2}(t)=\int_{\sigma}^{\theta(t)}\left(u\left(\xi, L^{2} k^{-2}(t-\xi)\right)+\lambda u\left(\xi-\sigma, L^{2} k^{-2}(t-\xi)-\tau\right)\right) d \xi  \tag{37}\\
& I_{3}(t)=\int_{\theta(t)}^{t} u\left(\xi, L^{2} k^{-2}(t-\xi)\right) d \xi  \tag{38}\\
& \text { and } \quad E_{3}(t)=\int_{\theta(t)}^{t} q\left(\xi-\sigma, L^{2} k^{-2}(t-\xi)-\tau\right) d \xi \tag{39}
\end{align*}
$$

Lemma 1 guarantees that the integrals $I_{1}(t), I_{2}(t)$ and $I_{3}(t)$ are linear integrals on the segments $A_{t} U_{t}, U_{t} V_{t}$ and $V_{t} B_{t}$ respectively, which are inside the first quadrant. Similarly, the integrals $E_{1}(t)$ and $E_{3}(t)$ are linear integrals on the segments $B_{t_{*}} D_{t_{*}}$ and $C_{t_{*}} A_{t_{*}}$, which are outside of the first quadrant.

On the zeros of the solutions to nonlinear hyperbolic equations with Delays 195

## 2. Main Results

The present results illustrate the important role of the function $W_{n}\left(t_{1}, t_{2}\right)$.
Theorem 1. Suppose that $\lambda \geq 0$ as well as the conditions (H) hold. Let $t_{1}$ be a number with $t_{1}>\rho$ and $u \in D\left(Q_{\rho}\right)$ be a solution to the problem (1), (2). If there is a number $t_{2}>\tilde{t}_{1}$ such that

$$
\begin{align*}
& W_{n}\left(t_{1}, t_{2}\right) \leq 0  \tag{40}\\
& E_{1}\left(t_{2}\right) \geq 0 \quad \text { and } \quad E_{3}\left(t_{2}\right) \geq 0 \tag{41}
\end{align*}
$$

then the solution $u$ is not positive in $Q\left(t_{1}, t_{2}\right]$.
Proof. Assume to the contrary, i. e. that:

$$
\begin{align*}
& \exists t_{2}>\tilde{t}_{1}: \quad W_{n}\left(t_{1}, t_{2}\right) \leq 0  \tag{42}\\
& \text { and that } \quad u(x, y)>0 \quad \forall(x, y) \in Q\left(t_{1}, t_{2}\right] \tag{43}
\end{align*}
$$

holds for the same $t_{1}$ and $t_{2}$. The proof consists of two parts. We prove that

$$
\begin{equation*}
t_{2} w_{n}\left(t_{2}\right)>0 \tag{44}
\end{equation*}
$$

in the first part. Then we prove that

$$
\begin{equation*}
t_{2} w_{n}\left(t_{2}\right) \leq W_{n}\left(t_{1}, t_{2}\right) \tag{45}
\end{equation*}
$$

in the second one.
We obtain the needed contradiction since the simultaneous consideration of (42), (44) and (45) leads to the impossible inequalities:

$$
\begin{equation*}
0<t_{2} w_{n}\left(t_{2}\right) \leq W_{n}\left(t_{1}, t_{2}\right) \leq 0 \tag{46}
\end{equation*}
$$

Let us begin with the first part, i. e. let us assume that (43) is fulfilled.
Lemma 2. Let all the conditions of Theorem 1 be satisfied as well as the inequality (43). Then (44) holds.

Proof. Since (43) holds, then together with Remark 4 and Lemma 1 we

$$
\begin{align*}
& \text { conclude that } u\left(\xi, L^{2} k^{-2}\left(t_{2}-\xi\right)\right)>0 \quad \forall \xi \in\left[0, t_{2}\right]  \tag{47}\\
& \text { and } \left.\quad u\left(\xi-\sigma, L^{2} k^{-2}\left(t_{2}-\xi\right)-\tau\right)\right)>0 \quad \forall \xi \in\left[\sigma, \theta\left(t_{2}\right)\right] . \tag{48}
\end{align*}
$$

First, we combine (47) and (48) with (35), (37) and (38): $I_{1}\left(t_{2}\right)+I_{2}\left(t_{2}\right)+I_{3}\left(t_{2}\right)=$ (49) $=\int_{0}^{t_{2}} u\left(\xi, L^{2} k^{-2}\left(t_{2}-\xi\right)\right) d \xi+\lambda \int_{\sigma}^{\theta\left(t_{2}\right)} u\left(\xi-\sigma, L^{2} k^{-2}\left(t_{2}-\xi\right)-\tau\right) d \xi>0$.

Further, we replace (49) and (41) in (34) in the particular case, where $t=t_{2}$ to establish (44).

Then we continue with the second part.
Lemma 3. Let the conditions (H) be satisfied and let the function $u$ be a solution of the problem (1), (2). Then

$$
\begin{align*}
& \left(t w_{n}(t)\right)^{\prime \prime}=p_{n}^{\prime}(t)+L^{2} k^{-2} q_{n}^{\prime}\left(L^{2} k^{-2} t\right)+ \\
& +L^{2} k^{-2} \int_{0}^{t}\left(u_{x y}\left(\xi, L^{2} k^{-2}(t-\xi)\right)+\lambda u_{x y}\left(\xi-\sigma, L^{2} k^{-2}(t-\xi)-\tau\right)\right) d \xi \tag{50}
\end{align*}
$$

Lemma 4. Let all the conditions of Theorem 1 hold and let the function $u$ be a positive solution of the problem (1), (2) in $Q\left(t_{1}, t_{2}\right]$. Then (45) is fulfilled.

Proof. First, we apply the condition H4 to (43) and establish that

$$
\begin{equation*}
c(x, y, \xi, \eta, \zeta) \geq 0 \quad \forall(x, y) \in Q\left(t_{1}, t_{2}\right] \tag{51}
\end{equation*}
$$

Secondary, we apply (51) to (1):

$$
u_{x y}\left(\xi, L^{2} k^{-2}(t-\xi)\right)+\lambda u_{x y}\left(\xi-\sigma, L^{2} k^{-2}(t-\xi)-\tau\right) \leq f\left(\xi, L^{2} k^{-2}(t-\xi)\right)
$$

i.e.

$$
\begin{equation*}
\left(t w_{n}(t)\right)^{\prime \prime} \leq p_{n}^{\prime}(t)+L^{2} k^{-2} q_{n}^{\prime}\left(L^{2} k^{-2} t\right)+L^{2} k^{-2} \int_{0}^{t} f\left(\xi, L^{2} k^{-2}(t-\xi)\right) d \xi \tag{52}
\end{equation*}
$$

because of Lemma 3. Further, we integrate two times the above inequality.
Theorem 2. Suppose that $\lambda \geq 0$ as well as the conditions $(H)$ hold. Let $t_{1}$ be a number with $t_{1}>\rho_{\tilde{\sim}}$ and $u \in D\left(Q_{\rho}\right)$ be a solution to the problem (1), (2). If there is a number $t_{2}>\tilde{t}_{1}$ such that

$$
\begin{align*}
& W_{n}\left(t_{1}, t_{2}\right) \geq 0  \tag{53}\\
& E_{1}\left(t_{2}\right) \leq 0 \quad \text { and } \quad E_{3}\left(t_{2}\right) \leq 0 \tag{54}
\end{align*}
$$

then the solution $u$ is not negative in $Q\left(t_{1}, t_{2}\right]$.

On the zeros of the solutions to nonlinear hyperbolic equations with Delays 197

Proof. Assume to the contrary, i. e. that:

$$
\exists t_{2}>\tilde{t}_{1}: \quad W_{n}\left(t_{1}, t_{2}\right) \geq 0 \quad \text { and } \quad u(x, y)<0 \quad \forall(x, y) \in Q\left(t_{1}, t_{2}\right]
$$

holds for the same $t_{1}$ and $t_{2}$. This time we establish that:

$$
\text { 1. } t_{2} w_{n}\left(t_{2}\right)<0 \quad \text { and } 2 . \quad t_{2} w_{n}\left(t_{2}\right) \geq W_{n}\left(t_{1}, t_{2}\right)
$$

to obtain a contradiction.
Theorem 3. Suppose that $\lambda \geq 0$ as well as the conditions $(H)$ hold. Let $t_{1}$ be a number with $t_{1}>\rho$ and $u \in D\left(Q_{\rho}\right)$ be a solution to the problem (1), (2). If there is a number $t_{2}>\tilde{t}_{1}$ such that

$$
\begin{align*}
& W_{n}\left(t_{1}, t_{2}\right)=0  \tag{55}\\
& E_{1}\left(t_{2}\right)=E_{3}\left(t_{2}\right)=0 \tag{56}
\end{align*}
$$

then the solution $u$ has a zero in $Q\left(t_{1}, t_{2}\right]$.
Proof. Everything here follows from Remark 6 and the above two theorems. Really, the condition (55) satisfies both (40) and (53). Also, the condition (56) satisfies both (41) and (54). Hence, we could apply Theorems 1 and 2. These theorems make us sure that the problem (1), (2) has nor positive solution in $Q\left(t_{1}, t_{2}\right]$ neither negative solution in $Q\left(t_{1}, t_{2}\right]$. Finally, we apply Remark 6 to finish the proof.

Theorem 4. Suppose that $\lambda \geq 0$ as well as the conditions (H) and

$$
\begin{equation*}
p(x, y)=q(x, y) \equiv 0, \quad \forall(x, y) \in \mathbf{S}_{\mathbf{1}} \bigcup \mathbf{S}_{\mathbf{2}} \tag{57}
\end{equation*}
$$

are satisfied. Let $t_{1}$ be a number with $t_{1}>\rho$ and $u \in D\left(Q_{\rho}\right)$ be a solution to the problem (1), (2). If there is a number $t_{2}>\tilde{t}_{1}$ such that (55) holds then the solution $u$ has a zero in $Q\left(t_{1}, t_{2}\right]$.

Proof. Since (57) guarantees that the functions $p(x, y)$ and $q(x, y)$ satisfy (56), then the present theorem is true because it is a particular case of the previous one.

Theorem 5. Suppose that $\lambda \geq 0$ and $(H)$ are fulfilled and let there exist two sequences $\left\{\tau_{m}\right\}_{m=1}^{\infty}$ and $\left\{\theta_{m}\right\}_{m=1}^{\infty}$ such that

$$
\begin{equation*}
\lim _{m \rightarrow \infty} \tau_{m}=+\infty \quad \text { and } \quad \lim _{m \rightarrow \infty} \theta_{m}=+\infty \tag{58}
\end{equation*}
$$

which satisfy the following conditions:

$$
\begin{align*}
& E_{1}\left(\theta_{m}\right)=E_{3}\left(\theta_{m}\right)=0  \tag{59}\\
& \theta_{m}>\tilde{\tau_{m}}, \quad \text { where } \tilde{\tau_{m}}=\tau_{m}+\sigma+\theta_{*}  \tag{60}\\
& \text { and } \quad W_{n}\left(\tau_{m}, \theta_{m}\right)=0 \tag{61}
\end{align*}
$$

$\forall m \in \mathbf{N}$. Then every solution $u \in D\left(Q_{\rho}\right)$ to the problem (1), (2) is oscillating in $Q_{\rho}$.

Proof. Since all the conditions of Theorem 3 are fulfilled in the particular case, where

$$
t_{1}=\tau_{m} \quad \text { and } \quad t_{2}=\theta_{m} \quad \forall m \in \mathbf{N}
$$

then the solution $u$ has a zero in $Q\left(\tau_{m}, \theta_{m}\right] \forall m \in \mathbf{N}$. In fact, the last one means just that the function $u$ is oscillating.

Theorem 6. Let $\lambda \geq 0$. Assume the conditions (H) hold as well as the condition

$$
\begin{equation*}
E_{1}(t)=E_{3}(t)=0 \quad \forall t \geq 0 \tag{62}
\end{equation*}
$$

Then every solution $u \in D\left(Q_{\rho}\right)$ to the problem (1), (2) is oscillating in $Q_{\rho}$ if

$$
\begin{align*}
& \liminf _{t \rightarrow \infty} \int_{T}^{t}(1-(s / t))\left(p_{n}^{\prime}(s)+L^{2} k^{-2} q_{n}^{\prime}\left(L^{2} k^{-2} s\right)+\right.  \tag{63}\\
& \left.+L^{2} k^{-2} \int_{0}^{s} f\left(\xi, L^{2} k^{-2}(s-\xi)\right) d \xi\right) d s=-\infty \quad \text { and } \\
& \limsup _{t \rightarrow \infty} \int_{T}^{t}(1-(s / t))\left(p_{n}^{\prime}(s)+L^{2} k^{-2} q_{n}^{\prime}\left(L^{2} k^{-2} s\right)+\right.  \tag{64}\\
& \left.\quad+L^{2} k^{-2} \int_{0}^{s} f\left(\xi, L^{2} k^{-2}(s-\xi)\right) d \xi\right) d s=+\infty
\end{align*}
$$

for all large $T$.
Proof. The hypotheses give us that for every arbitrary fixed first argument $\tilde{t}_{*}$ of $W_{n}(\tilde{t}, t)$ there exist two second arguments $t_{* 1}$ and $t_{* 2}$ in which this continuous function of two arguments has opposite signs. Consequently, from the well known theorem there exists a number $t_{*}$ between $t_{* 1}$ and $t_{* 2}$ such that $W_{n}\left(\tilde{t}_{*}, t_{*}\right)=0$ and we apply Theorem 5.
